ACKNOWLEDGEMENTS

This report was prepared by P. Kiely, Data Analyst, Air Resources Branch, Ministry of the Environment, (MOE).

The data analysed in this report were collected by Moniteq Limited (under contract to Stelco Inc., Texaco Canada Inc. and the Ministry of the Environment), as well as by Ontario Hydro and the Ministry of the Environment's West Central Region.

Comments on the manuscript by Keith Heidorn of the Air Resources Branch and members of the NEMP Technical Committee are gratefully acknowledged.

Special thanks are due to William Chang for his computer programming support.

ACKNOWLEDGEMENTS

The report was prepared by B. Klein, Data Analyst, Air Resources
Branch, Ministry of the Environment (MCE).

The data entered in this report were collected by Monitor Limited
under contract to the Province of Ontario, Canada Inc. and the Ministry of the
Environment, as well as by Ontario Hydro and the Ministry of the Environment's
Water Control Division.

Comments on the manuscript by Keith Hudson of the Air Resources
Branch and members of the MCE's Technical Committee are gratefully
acknowledged.

Special thanks are due to William Camp for his computer
programming - CMC.

1. **INTRODUCTION**

The Nanticoke Environmental Management Program (NEMP) is a co-ordinated study into the impact of industrial development in the Nanticoke area on air quality in the Haldimand-Norfolk region. It is jointly sponsored by the Federal and Provincial governments, Ontario Hydro, Stelco and Texaco. The NEMP monitoring network, established in the fall of 1978, was operated throughout 1981 to measure adherence to air quality criteria (AQC) for the protection of human health and comfort as well as that of vegetation, animal life and property. In addition to the NEMP network, Ontario Hydro has been operating an SO₂ network of approximately 16 monitors since 1970 and MOE West-Central Region has been operating gaseous monitors at Chesapeake and Simcoe as well as a hi-vol network consisting of 6 samplers.

The Haldimand-Norfolk region is situated on the northern shore of Lake Erie in the midst of a major industrial complex comprised of a thermal generating station, a steel plant and an oil refinery. Ontario Hydro, Stelco and Texaco operated throughout most of 1981. Table 1 outlines the major emission sources and their 1981 emission estimates for sulfur dioxide and particulate matter. Emissions from Ontario Hydro's generating station are released from two 198-metre stacks (separated by 275 m), whereas emissions from Stelco and Texaco emanate from stacks as well as low-level sources. Monitoring stations have been located according to criteria that take into account predominant wind patterns and source configuration, as well as in response to concerned citizens. The network configuration for 1981 remained the same as for 1980 except for the relocation of a hi-vol sampler (SW37 moved to SW40) in January. Figure 1 shows the location of monitoring stations and Table 2 lists the parameters monitored at each location.

This report complements the second data summary report covering network data up to December 1980 (4) and summarizes the data collected by the NEMP network during 1981.

2.0 Gaseous Data Analysis

2.1 Analysis of Sulfur Dioxide (SO₂) Data:

Hourly averaged SO₂ concentrations were monitored at twenty locations during 1981. Sixteen stations were operated by Ontario Hydro, two by MOE's West Central Region and two by the NEMP network. Once again, the percentage of valid data for the entire network was in excess of 90.0. Figure 2 shows the annual frequency distribution of hourly averaged SO₂ concentrations for 1981. Table 3 summarizes the SO₂ annual average concentrations for individual stations. The annual averaged values at all stations for 1981 were well below the 20 ppb criterion. The highest annual average in 1981 was recorded at NNE05 (7ppb).

Seasonal frequency distribution of the hourly SO₂ concentrations is shown in Figure 3. Highest averaged SO₂ concentrations occur during the winter period. Ninety percent of the time the hourly averaged SO₂ values (for the winter period of 1981) did not exceed 30 ppb. During the spring, summer and fall seasons, the ninety percentile coincided with 10 ppb.

Table 4 shows the number of network exceedances of the hourly AQC (250 ppb) for the period 1975 to 1981. There were nineteen hours during 1981 when the hourly AQC was exceeded. Details of the exceedance hours are presented in Table 5. Except for one occasion, monitors showing AQC exceedances were located downwind of the Hydro generating station. On August 26, 1981, an exceedance was recorded at monitor E05 however, winds at the time of exceedance were light (10km/hr) from the east-southeast, making source identification difficult. Stable atmospheric conditions (as indicated by low mixed layer heights) and light and variable winds (70° windshift prior to exceedance hour) contributed to poor dispersion characteristics on this date.

There were no exceedances of the daily AQC (100 ppb) during 1981.

2.2 Analysis of Ozone (O₃) Data:

The annual frequency distribution of the hourly averaged ozone concentrations for SW37, NNE39 and WNW19 is shown in Figure 4. The annual

average ozone concentration was highest at SW37 (31 ppb) and decreased inland, (24 ppb at NNE39). A similar trend was apparent in previous years, Table 6. At monitor SW37, WNW19 and NNE39, the ninety percentile coincided with 55, 50 and 43 ppb respectively.

Seasonal frequency distribution of the hourly O_3 concentrations is shown in Figure 5. Ozone levels are highest in the summer season due to predominant southerly winds, clear skies and strong insolation. Ninety percent of the time during the winter, spring, summer and fall, the ozone concentrations (for the entire network) did not exceed 30, 50, 69 and 39 ppb respectively.

During 1981, there were a total of 341 exceedances of the AQC for ozone (80 ppb). As in previous years, SW37 had the maximum number of exceedances at 159, WNW19 reported 138, and NNE39 reported 44. Exceedances were reported on 35 days during 1981. Thirty of these days were during the growing season (June to September).

2.3 Analysis of Nitrogen Dioxide (NO_2) Data:

Nitric oxide (NO) concentrations were subtracted from total nitrogen oxide (NO_x) values to obtain the hourly NO_2 values. Nitrogen oxides were measured at five locations, (SW37, NNE39, NO7, WNW19 and NNE10). Annual average concentrations were below 14 ppb (Table 7). The maximum hourly concentration (100 ppb) was recorded at NNE10. Annual frequency distribution of the hourly averaged NO_2 concentrations is shown in Figure 6. Ninety percent of the time the NO_2 concentrations did not exceed 20 ppb. There were no exceedances of the one hour (200 ppb) or the 24 hour (100 ppb) AQC during 1981.

2.4 Analysis of Total Reduced Sulfur (TRS) Data:

TRS was monitored at four locations, (NNE10, NNE05, NNW08 and WNW03) during 1981. Annual frequency distribution of the hourly averaged TRS concentrations is shown in Figure 7. As in previous years, the annual average for the TRS network was less than 1 ppb. Concentrations were highest at the Nanticoke Village monitor (WNW03). The ninety-nine percentile for WNW03 coincides with 6 ppb compared with 3, 3 and 2 ppb at NNE10, NNE05 and NNW08

respectively. Also, the maximum hourly concentration (36 ppb) was recorded at monitor WNW03, (Table 8). On March 29, 1981, hourly concentrations (18-36 ppb range) were observed for the period 0100 to 0600 EST at WNW03. Surface winds (as monitored by the 10 m level of the Jarvis meteorological tower) were from the southwest at 25 km/hour during this period. Thus Stelco was the likely source of this TRS event.

2.5 Analysis of Carbon Monoxide (CO) Data:

Carbon monoxide monitoring continued at NNE39 and SW37 throughout 1981. Figure 8 shows the yearly frequency distribution of hourly averaged CO concentrations for 1981. Ninety-nine percent of the time the CO concentrations did not exceed 1 ppm (Table 9). The hourly (30 ppm) and eight-hourly (13 ppm) AQC for CO was never exceeded during 1981.

2.6 Analysis of Hydrocarbon Methane CH₄ and Non-Methane MNHC Data:

Figures 9 and 10 show the annual network (NNE10, NNE05 and NNW08) frequency distribution of methane and non-methane hydrocarbons. The annual average concentrations for CH₄ and NMHC are summarized in Table 10 and 11 respectively.

It should be noted here that during the latter part of 1981, non-methane concentrations were observed to increase, especially at NNE10 and NNW08. After intensive investigation and consultation with the manufacturer, it was determined that there was excessive electrical noise which affected the zero calibration of the instrument. So far no cure has been found for this problem. This places some doubt on the validity of the observed values. A longer calibration period (up to 4 hours) is being tried so that the electrical interference is eliminated. If this procedure is successful in eliminating the noise it may be possible to correct the previous data set.

3.0 Airborne Particulates Data:

The particulate monitoring network in the Nanticoke area during 1981 consisted of 14 hi-vol samplers, operated by NEMP (Figure 11). In January of 1981, the sampler at SW37 was relocated at SW40 to help alleviate the problem of wind blown dust at the former location. Glass fibre filters were used at all locations with parallel sampling on Whatman 41 cellulose filters at eight stations. TSP measurements were carried out on the glass fibre filters while a detailed chemical analysis was done on selected Whatman 41 filters. Some of the glass fibre filters were also analysed for polynuclear aromatic hydrocarbons (PAH) and inorganic (CF) and total carbon (CT). A six day sampling cycle was used at all stations except for the hi-vol samplers at W07, NW03 and NNW06, which operated on a three day cycle to monitor the Stelco emissions. Sampling periods were 24-hours in duration. The chemical analyses results of the selected Whatman 41 filters collected during 1981 for the entire NEMP network are listed in Appendix 1. PAH results and total and free carbon results are also listed by station for 1981 in Appendix 1.

Suspended particulates are summarized by station in Table 12. Annual geometric means were in the 30 to 40 $\mu\text{g}/\text{m}^3$ range. The annual and seasonal frequency distributions of TSP for the entire NEMP network during 1981 are shown in Figures 12 and 13. Monthly geometric means for the NEMP network TSP data (1979-1981) are plotted in Figure 14. The monthly trend in TSP levels has been similar for all three years data. Concentrations are higher during the May to September period compared with the October to April period.

There were no exceedances of the annual AQC ($60 \mu\text{g}/\text{m}^3$) for TSP during 1981 however, there were 10 exceedances of the daily AQC ($120 \mu\text{g}/\text{m}^3$). On May 22, 1981, TSP exceedances were recorded at seven different monitoring locations throughout the NEMP network. The maximum concentration was observed at NW03 ($184 \mu\text{g}/\text{m}^3$). The following monitors also recorded elevated TSP on May 22; N17 (129), W07 (155), NE 27 (121), NE16 (121), NE41 (141), and NNE22 (124). Surface winds (as measured by the 10 m level of the Jarvis meteorological tower) were from the northwest at 18 km/hour. TSP levels were high throughout the entire West-Central region on this day. A high pressure system, centred over southern Ontario, created a widespread subsidence inversion. Local as well as long range pollution was trapped below the inversion

layer. The remaining three exceedances in 1981 occurred at NNW06. On May 4, the surface winds were from the southerly quadrant making Stelco the probable source. On June 30, agricultural activity adjacent to the sampling station caused the elevated TSP. Finally, on August 26, the surface winds were light and variable making source identification difficult.

Annual and seasonal means for sulfate, nitrate, calcium, magnesium and total carbon levels are shown in Table 13. Data for all three years of network operation (1979, 1980 and 1981) have been included for comparison purposes. Annual means for all five parameters are comparable to those observed in other years. As in previous years, sulfate and total carbon concentrations are highest during the summer season.

During 1981, sulfate, nitrate and total carbon concentrations are higher for southerly versus northerly winds (Table 14).

4.0 Precipitation Data:

The NEMP precipitation network continued throughout 1981 to collect monthly samples at six sites in the Nanticoke region (Figure 15). Precipitation samples are analyzed for pH, major ions, some nutrients and trace metals. Chemical analysis results for all 1981 precipitation samples are listed in Appendix 2.

Network averaged pH, selected major ion and trace metal concentrations are listed in Table 15. For comparison purposes 1979 and 1980 concentrations are also shown.

It may be noted that, with the exception of Zn, there has been little annual variation in the precipitation concentrations. The earlier high values for Zn are now thought to be an artifact, due to sampling and analysis errors. Table 15 also shows "representative" values of all the above parameters for the general MOE West-Central region, which come from data obtained by the Acid Precipitation in Ontario Study (APIOS) (6). Since APIOS sites have been carefully chosen to be representative of "background" conditions (free from local sources of pollution), a comparison of NEMP and APIOS values should indicate whether there is a local impact of industrial activity on the precipitation quality. Generally, there is no indication in the data of any local impact, as can be seen from the last two columns of Table 15.

5.0 Summary

This report summarizes the 1981 gaseous data collected by the NEMP, Ontario Hydro and MOE West Central Region networks as well as the 1981 particulate and precipitation data collected by the NEMP network.

The hourly (250 ppb) AQC for SO_2 was exceeded 19 times during 1981. There were no exceedances of the daily (100 ppb) AQC for SO_2 . The annual average values at all stations for 1981 were less than half of the annual criterion (20 ppb).

The ozone network recorded 341 hourly exceedances of the ozone AQC (80 pb), 159 at SW37, 138 at WNW19 and only 44 at NNE39.

As in previous years, NO_2 and CO levels were well below their respective AQC during 1981.

Annual average TRS concentrations were less than 1 ppb for all four monitors.

The annual average for methane and non-methane hydrocarbon was less than 2 ppm and 1 ppm respectively.

There were 10 TSP exceedances of the daily (120 ug/m^3) AQC during 1981. Seven of these exceedances occurred on the same day (May 22) and were associated with local as well as long range pollution due to a subsidence inversion. Sulfate, nitrate and total carbon concentrations were higher for southerly versus northerly winds.

pH for wet deposition in the NEMP network during 1981 was 4.1.

Ambient air quality in the Haldimand-Norfolk Region continued to be satisfactory throughout 1981.

Appendix 1

**NEMP PARTICULATES DATA COLLECTED
DURING JANUARY TO DECEMBER 1981.**

Sampling dates were chosen according to the daily wind direction. Wind directions were obtained from the 10 m level of the Jarvis meteorological tower. The most frequent direction during the 24 hour sampling period was used. (N/A) corresponds to invalid or missing data while (BDL) represents concentrations reported as below the detection limit. Geometric means were not calculated for elements which reported in excess of 25% of the data below the detection limit. If less than 25 % of the data are below the detection limit then one half the value of the detection limit was used to calculate the geometric mean. All concentrations are expressed in $\mu\text{g}/\text{m}^3$ and are listed station by station. The PAH results for both 1980 and 1981 are included in the Appendix. During 1981 complete PAH results are available for the three stations closest to Stelco (22953, 22961 and 22963) and for the other 5 stations, composite sample results, according to meteorological conditons, have been reported. It is known that PAH sampling on glass fibre filters leaves some doubt as to the validity of the results. PAH loss (anywhere from 20% for Benzo(ghi)Perylene to 85% for Fluorothene) is due to volatilization and oxidation of the PAH compounds on the hi-vol filter (1).

It should also be noted here that, due to the interference between nitric acid and free carbon (during laboratory analysis), the free carbon results and the free carbon to total carbon ratios are somewhat less than expected.

Concentrations are in ug/g3

Bracketed numbers indicate the number of individual samples within the composite

Appendix 2

NEMP PRECIPITATION DATA COLLECTED DURING JANUARY TO DECEMBER 1981.

Data are presented on a monthly basis according to sampling station. All concentrations are expressed in mg/l except precipitation volume which is expressed in ml. Total acidity is expressed as CaCO_3 . (N/A) represents missing or unavailable data. The NO_3^- and NH_4^+ concentrations are expressed as N- NO_3^- and N- NH_4^+ respectively.

PK/en/AR33-3
